

New York City TLC Project Preliminary Data Summary

Executive summary report
Commission Prepared by **Automatidata**

OVERVIEW

This project focuses on analyzing the New York City TLC dataset to clean the data and uncover key patterns in trip costs and behaviors. The goal is to prepare the dataset for predictive modeling by identifying data quality issues and understanding what drives ride fares.

PROJECT STATUS

- The data has been loaded and reviewed for structural issues, data types, and statistical anomalies
- We have completed the initial data inspection.

NEXT STEPS

1. Conduct a complete exploratory data analysis.
2. handle extreme outliers, and negative payment values
3. Change the time columns into standard datetime objects for better analysis.

KEY INSIGHTS

- The pickup and dropoff times are currently saved as text (strings) and need to be changed to a proper datetime format.
- The dataset contains negative values for charges like `fare_amount` and `total_amount`, which represent incorrect data or errors.
- Some trips show massive cost anomalies, such as a 2.60-mile trip that cost over \$1,200 due to an extreme fare and tip.
- The longest trips are not always the most expensive.
